

AXIS Device Manager

Introduction

The importance of cybersecurity continues to increase in the surveillance and security sectors. Effective cybersecurity requires ensuring a sufficient depth of defense to properly protect your IP network at every level, from the products and partners you choose, to the requirements both you and they set.

This guide describes how you can use AXIS Device Manager to harden your system and increase security. It focuses on key aspects and describes recommendations.

Device lifecycle management

At Axis, we understand the importance of a strong security foundation throughout the device's entire lifecycle. Our commitment to cybersecurity ensures that our products and solutions provide robust protection against potential threats.

Implementation

Axis provides secure-by-design devices with built-in security features, such as secure boot mechanisms, a signed operating system and encrypted storage. Additionally, AXIS Device Manager helps installers and system administrators securely configure and deploy devices, ensuring a secure setup right from the start.

Active service

During the operational phase, Axis offers regular device software updates and security patches to protect against vulnerabilities. AXIS Device Manager also enables remote monitoring and maintenance, allowing for swift issue resolution and minimum downtime. Furthermore, our Hardening Guides provide recommendations for configuring devices to meet specific security requirements.

Decommissioning

When it's time to retire or replace devices, AXIS Device Manager facilitates secure decommissioning by wiping sensitive data and restoring devices to their factory settings. This ensures that no confidential information remains on the device, protecting user data and preventing unauthorized access.

AXIS Device Manager

AXIS Device Manager is an on-premises tool that provides an easy, cost-effective and cyber-secure way to manage all major installation, security and maintenance tasks (see the table below). The tool is suitable for managing up to a couple of thousand Axis devices on a single site, or for several thousand devices spread over multiple sites. AXIS Device Manager enables you to efficiently deploy cybersecurity controls to protect your network devices and align them to a security infrastructure.

Device management functions, AXIS Device Manager

Installation	Maintenance
Assign IP address	Device status
Export device list and keep track of assets*	Collect device data
User and password management*	Configure devices and copy configurations to multiple devices
ACAP management	Connect to multiple servers/systems
Upgrade AXIS OS, based on LTS or Active*	Restore points
HTTPS certificate management*	Restore factory default settings
Manage IEEE 802.1 certificates ^{*/**}	Replace device(s)

Device tagging	Certificate renewal and management*
	Cybersecurity hardening*

* Indicates cybersecurity control function.

** Active Directory Certificate Services not currently supported. Validated for FreeRADIUS running on Linux.

Multi-site management.

AXIS OS upgrade.

Certificate management.

Device inventory

A fundamental aspect of ensuring the security of an enterprise network is maintaining a complete inventory of the devices residing on the network. When creating or reviewing an overall security policy, it is important to have knowledge of and clear documentation for each and every device – not just the critical assets. This is because any overlooked device can be a means of entry for attackers. You can't protect devices that you overlook or are not fully aware of.

A device inventory represents an essential step in securing an enterprise network. AXIS Device Manager can help you here, as it:

- Gives you easy access to a current, complete inventory of your network devices when working with audits and incident responders.
- Provides a complete list of your devices, which can be sorted by total number, type, model numbers, etc.
- Gives you the status of every device on your network.
- Helps you plan ahead, by showing when device software support is scheduled to end, as well as listing which newer product(s) can be used as replacements.

Alarms and Tasks

AXIS Device Manager provides a clear view of your inventory of devices.

AXIS Device Manager provides the automated means to access a real-time inventory of Axis network devices. It lets you automatically identify, list and sort your devices. Equally importantly, it lets you use tags to group and sort devices based on your own criteria, making it easy to get an overview of and document all the Axis devices on your network.

Account and password policy

Authentication and privilege control is an important part of protecting network resources. Implementing policy helps reduce the risk of accidental or deliberate misuse over time. Enforcing the use of robust passwords is a key task, but so is reducing the risk of compromised passwords. Device passwords often spread within an organization, and when they do you lose control over who has access to them. AXIS Device Manager helps you easily manage multiple accounts and passwords for Axis devices.

Why you should have more than one user account in devices:

- You control privilege levels for different user types (machines and humans).
- You reduce the risk of compromising the root (master) password.
- You can reset credentials for one user type without impacting others.

Working with privileges in AXIS Device Manager

Axis devices support multiple accounts, with each account having one of three different privilege levels:

- **Viewers:** These users have access to video and PTZ control.
- **Operators:** Users with operator rights may optimize camera settings and video stream profiles.
- **Administrators:** Administrators can administer accounts, modify network settings and control a number of services in the device.

Each role accessing the camera should have its own account. For example, you might configure the role "Control room personnel" with the privilege level "operator", whereas the role "Patrolling staff" might only need the privilege level "viewer".

Recommended steps

- Before adding cameras to the VMS – add the cameras to AXIS Device Manager.
- In AXIS Device Manager, select all cameras and create a new user account called "vms" or similar and set a strong password. The privileges need to align with the requirements of the VMS – this could be either operator or administrator (check with the manufacturer).
- Add the devices to the VMS with the account and password you created.
- Back in AXIS Device Manager – select all the cameras again and reset (change) the "root" account password with a new, strong password. The "root" account password should be known only to a limited number of individuals (those who use AXIS Device Manager).
- When someone needs to use a web browser to access a device for maintenance or troubleshooting tasks, do **not** give them the root password. Instead, use AXIS Device Manager to create a new (temporary) account for the selected device(s), with either administrator or operator privileges. When their work is complete, use AXIS Device Manager to delete the temporary account.
- AXIS Device Manager supports local administrators as well as domain users and groups. You can use a local administrator if the AXIS Device Manager client will only be accessed from the same machine hosting the AXIS Device Manager server. We recommend using domain users if the person maintaining the system will be using remote clients.

AXIS OS upgrades

Updated AXIS OS versions include patches for known vulnerabilities. It is essential to always use the latest software because attackers may try to exploit known vulnerabilities. Equally importantly, rapid deployment of a new AXIS OS version boosts operational capabilities and removes bottlenecks related to manually rolling out new release upgrades. AXIS Device Manager connects to www.axis.com and downloads the latest applicable AXIS OS or service releases. If you prefer to not download directly to your network from the internet, you can save upgrades to a USB stick and then upload them to your AXIS Device Manager client. It also shows if new AXIS OS versions are available and lets you quickly deploy them on Axis devices.

Why you should always run the latest AXIS OS versions:

- Your network and devices are protected with the latest patches against known vulnerabilities, especially critical ones.
- Your devices are updated for the latest performance improvements, as well as fixes for bugs and flaws.
- You get immediate access to the latest features and functionality enhancements.

The screenshot displays the AXIS Device Manager Client interface. The main window, titled 'Manage devices', shows a list of 250 devices with columns for MAC address, Status, Address, and Model. An 'Upgrade Firmware' dialog box is open, titled 'Select firmware versions for upgrade'. This dialog contains a table with the following columns: Model, Quantity, Firmware, and Upgrade. The table lists various Axis models and their current firmware versions, along with the latest available version and a 'Download' button. A 'Select / Deselect all' checkbox is located at the bottom of the table. To the right of the dialog, a 'Device replacements' table is visible, showing the end of software support for various models and the recommended replacement models.

Model	Quantity	Firmware	Upgrade
☐ AXIS Q9216-SLV	1	11.11.160	11.11.160 (AXIS OS LTS 2024)

Upgrading AXIS OS with AXIS Device Manager is simplified thanks to on-screen notifications and intuitive dialog boxes.

Additional hardening

Employing a good user- and password policy, as well as running up-to-date AXIS OS versions, will mitigate common risks for devices. The *AXIS Hardening Guide* describes additional measures to reduce risks within large and critical organizations. This includes disabling services that may not be used and enabling services that can help detect and monitor indication of an attack or breach. AXIS Device Manager simplifies the process of deploying some of these policies. Axis provides a configuration template for basic recommended settings.

How to harden devices according to the Axis Hardening Guide:

- Read the *AXIS Hardening Guide* and download the template file at the end of the document.
- Edit the configuration file to select relevant items.
- Select devices in AXIS Device Manager inventory.
- Right-click and select "Configure Devices > Configure..."
- Click "Configuration File" and select the downloaded file.
- Adjust the settings as required.

Certificate lifecycle management

Certificate lifecycle management is a means of cost-efficiently handling all processes and tasks related to issuing, installing, inspecting, remediating and renewing certificates over time. AXIS Device Manager enables you to efficiently manage certificates by allowing administrators to:

- Issue CA-signed certificates when no other CA is available
- Easily manage IEEE 802.1X certificates
- Easily manage HTTPS certificates
- Monitor certificate expiration dates
- Easily renew certificates prior to expiration

Recommendations for private root and intermediate CAs

It is not recommended to expose Axis devices as public servers targeting the public. This is why using a public CA for private resources is not cost-effective.

For HTTPS, the VMS server is the only client that needs to validate that it is accessing a trusted camera. Operator clients will never access the cameras directly, as live and recorded video is provided by the VMS server. In this situation there is limited value in incorporating camera server certificates in an existing enterprise PKI.

Using AXIS Device Manager as a private CA is the most cost-effective solution. After a root CA certificate is generated, install the AXIS Device Manager certificate in the VMS server's certificate store. If there are other clients accessing cameras directly (for maintenance or troubleshooting), install the AXIS Device Manager root CA in those clients as well.

For 802.1X, the camera needs a client certificate in order to authenticate itself to a RADIUS server. It is recommended to have the administrator for the Enterprise PKI/CA generate an Intermediate CA certificate and export this as a PKCS#12 (P12) certificate that can be installed in AXIS Device Manager.

For support in setting up a FreeRADIUS server, please visit the *Technical papers section* for AXIS Device Manager

Managing HTTPS certificates involves: 1) generating intermediate or root CA certificate in AXIS Device Manager; 2) exporting CA certificate to the VMS, and 3) uploading server certificates to the devices.

Using a Private CA. Managing IEEE 802.1X certificates involves: 1) generating intermediate CA and client certificate; 2) installing CA certificate on the Radius server; 3) importing CA certificate in AXIS Device Manager and 4) uploading CA and client certificates to the devices.

Using AXIS Device Manager as a CA. To manage IEEE 802.1X certificates: 1) generate the root CA certificate in AXIS Device Manager; 2) import the authentication CA certificate in AXIS Device Manager; 3) install the CA certificate on the Radius server; 4) upload the CA authentication and client certificates to the devices.

Conclusion

Security management and security control are important parts of implementing an effective cybersecurity approach. Each is a continuous process that demands maintaining clear status and following proper actions to mitigate any potential threat that may impact your IP network. AXIS Device Manager offers you a tool to both manage your devices as well as increase the security of your network. Contact your local Axis representative or go to www.axis.com for more information or support.
